1 Abstract

2 Individual contributions

The whole project was completed as a team. For sure we took into consideration all the personal backgrounds and knowledge. That is the reason why Raphael and Manuela focused on implenting the computer code. Whereas Andreas and Fabian concentrated on providing background information, compared the results with the reality and doing its verification.

3 Introduction and Motivations

3.1 Introduction

The evacuation of a passenger liner due to fire, sinking or other issues leads to several problems. A large amount of passengers try to save their lives and get to a rescue boat. Narrow and branched floors, smoke, inflowing water, the absence of illumination, rude passengers and so forth can make the evacuation difficult and reduce the number of survivors. There are a lot of norms how to minimize the harm of such an evacuation. For example there are rules on the number of rescue boats dependent on the amount of passengers [4]. With dry runs the staff is prepared for the case of emergency et cetera. In real life ship corridor reproduction, the behavior of distressed people is studied. Another approach is to model such ship evacuations numerically on the computer. As an example the software maritimeEXODUS by a development team from the University of Greenwich is a PC based evacuation and pedestrian dynamics model that is capable of simulating individual people, behaviour and vessel details. The model includes aspects of people-people, people-structure and people-environment interaction. It is capable of simulating thousands of people in very large ship geometries and can incorporate interaction with fire hazard data such as smoke, heat and toxic gases and angle of heel [7]. Our approach is similarly to model a passenger ship with a common geometrical outline and ground view. In an optimization process we will thereafter look for an ideal ground view, rescue boat distribution and their size to minimize the time needed for evacuation. Finally we will make a statement on possible improvements.

3.2 Motivation

Even though modern ocean liners are considered to be safe, the latest occasions attested that there is still potential for evacuation and safety improvements [8]. Certainly we know that this science is very advanced and practised since the sinking of the Titanic. Nevertheless knowing that there are still bottlenecks on the ships we are very motivated to detect and eliminate them with our mathematical models.

3.3 Fundamental Questions

To find these bottlenecks we run a mathematical model of a ship structure with several decks and its passengers [6]. After we localised these places we are interested in the answers of the following questions:

How much time can be saved by varying the dependent variables mentioned below:

- How much people can be saved by changing the disposition of the specific room types?
- Where are the bottlenecks during the evacuation? How can they be avoided?

What is the influence of the rescue boats?

- Are small or bigger boats better?
- Where do they have to be positioned?

If we have time to spare we analyse the difference between uncontrolled and controlled passenger flow:

- Is the crew able to prevent chaos in the evacuation process?
- What is the best way to lead the passengers out of the ship?

In addition we are keen to know if our model is a good abstraction of the reality?

4 Description of the model

We base our model on the work done by a group of former "MSSSM" students, by name Hans Hardmeier, Andrin Jenal, Beat Kueng and Felix Thaler [3]. In their work "Modeling Situations of Evacuation in a Multi-level Building" they wrote a computer program in the language C with a MATLAB interface to rapidly simulate the evacuation of multi-level buildings.

4.1 Social force model

Our approach is the social force model described by Helbing, Farkas and Vicsek [2]. In order to observe an escape panic situation and especially bottlenecks, they built up a continuous-space model. In mathematical terms they took Newton's second law and introduced a mix of socio psychological and physical forces for each so called pedestrian.

$$m_i \frac{d\mathbf{v}_i}{dt} = m_i f_D + \sum_{j(\neq i)} f_{ij} + \sum_W f_{iW} \quad (1)$$

Each pedestrian has his own mass and a direction e_i^0 in which he wants to move with a certain velocity v_i^0 . He tries to adapt his own velocity to the wanted velocity with a given characteristic time τ_i .

$$f_D = \frac{v_i^0(t) \mathbf{e}_i^0(t) - \mathbf{v}_i(t)}{\tau_i} \quad (2)$$

There are additionally interaction forces f_{ij} between the pedestrian and other people including an exponential part for the tendency of two pedestrians to stay away from each other. The second and third term are zero if the two pedestrians are not in touch. Elsewise there is a force in tangential direction t and in radial direction away from each other.

$$f_{ij} = \{A_i \exp[(r_{ij} - d_{ij})/B_i] + kg(r_{ij} - d_{ij})\} \mathbf{n}_{ij} + \kappa g(r_{ij} - d_{ij}) \Delta v_{ji}^t \mathbf{t}_{ij} \quad (3)$$

To be able to handle with walls there is another force f_{iW} introduced. Its direction is away from the surrounding walls and the structure is similar to the one for the interaction between pedestrians.

$$f_{iW} = \{A_i \exp[(r_i - d_{iW})/B_i] + kg(r_i - d_{iW})\} \mathbf{n}_{iW} - \kappa g(r_i - d_{iW}) (\mathbf{v}_i \cdot \mathbf{t}_{iW}) \mathbf{t}_{iW} \quad (4)$$

4.2 Ship structure

To apply the force model on a realistic situation a ship has to be implemented as well. Floor plans from the Costa Serena were taken [6]. In order to make strong conclusions we want to keep the following variables independent:

- Number of passengers (4400 agents)
- Overall capacity of the rescue boats (4680 seats)
- Ship size and outer shape

In order to optimize the evacuation time, we change the following dependent variables:

- Stairs and their positions
- Rescue boat size, number and position
- Control of the passenger flow by crew members (e.g. is there staff to lead the passengers and how are they doing it?)

5 Implementation

As mentioned above our code is based on the work of a previous project. Working on a different problem statement we had to make several adjustments and adapt it to our simulation model. In this chapter we will explain the most significant modifications we made. For the exact understanding of the original code and the process of optimization, please refer to the documentation of the previous project group, especially chapter five and nine[3] or our code in the Appendix.

5.1 Basic code

The builders of the code we base on created a flexible model to simulate building structures. The floors can be feed as graphic data into the system where different colors stand for different areas. Black are walls, red stairs up, blue stairs down, green exits and purple agent spawning areas. The data is evaluated in matlab in matrices. Information on parameters such as timestep, simulation time, force characteristics et cetera can be read in using a config file which is evaluated on simulation start. With a fast sweeping algorithm in C a vector field is created for every floor pointing in direction of the shortest way towards stairs and exits. In a loop over all passengers the acting forces on them are calculated and via forward Euler converted into velocities.

$$\mathbf{v}_{i,new} = \mathbf{v}_{i,previous} + \frac{\sum f}{m_i} dt \quad (5)$$

Again with the forward Euler scheme positions are calculated that were reached in a finite timestep.

$$\mathbf{r}_{i,new} = \mathbf{r}_{i,previous} + \mathbf{v}_{i,new} dt \quad (6)$$

5.2 Code adjustments

This subsection is intended to illustrate the modifications in the code. We explain the difference between our model and the one used in [3] and therefore the reason a modification was nessecary. Further we define the assumptions we made to minimize the modifications. Finally we specify the modifications and where they take place. Those parts are however not essential for the results of our reserch. They are ment to be an assistance for continuative projects.

5.2.1 Exits

Reason:

The first change which was necessary was due to the fact that the exits in our simulation are not simply on the lowest floor.

Assumption:

In the case of an emergency all agents are keen to leave the ship as fast as possible. Therefore in our simulation all passengers above the exit floor are only enabled to move down and passengers lower than the exit floor move upstairs.

Function:

applyForcesAndMove.m

New variables:

To define the floor in which the exits are we introduced a new variable *floor_exit* in the config file.

Modifications:

Since we defined our exit, we are able to easily modify the code by splitting the loop, in which the force-calculation and the movement of the agents take place, in two parts. First we loop over all floors higher than the exit floor. In those the agents are only allowed to move down. Secondly we do the same for all people in the floors lower than the exit floor where the passengers only can move up. The only floor left is the exit floor where the agents only move towards exits.

Because of this modification it is not necessary to loop twice over all floors. Consequently our code remains fast and efficient. We also kept the simple concept of vectors out of booleans. Means for each agent there is one number set:

- If the agent reaches a staircase and therefore changes the floor 1 is stored in the logical array *floorchange*
- otherwise a 0 is stored

The assumption is also a very helpful simplification for the pictures since we do not have to mess with the problem of stairs overlapping.

5.2.2 Different exits

Reason:

In our model the exits are the rescueboats, which can only hold a limited number of agents. Therefore we had to find a way how to differ the exits from each other and to assign a specific number to every exit. This number defines how many agents can stay on that rescueboat.

Function:

loadConfig.m

New variables:

- exit_count*, to define the number of exits.
- For each exit *k* a variable *exit_k_nr*, to define the number of agents it can hold.
- To store how many agents can exit in one specific exit, we introduced a matrix *exit_nr matrix*, where the number of agents that can exit is indicated for each pixel.

Modifications:

Some changes in the decoding of the pictures were necessary. The aim was to change as little as possible to the original code. It was clear that we are going to need as many different colors as we have different exits, to be able to distinguish them during the simulation.

We define every pixel which has red value=0, blue value=0 and green value unequal to zero a "exit-pixel". Now we can specify a lot of different colored exits by using green values between 256 and 256-*exit_count*.

We implemented the matrix *exit_nr* similar to the already existing one *img_exit*, in which we store a count to number the different exits. The number is defined by the green value of the pixel that belongs to this exit.

```
%make a zeros matrix as big as img_exit
config.exit_nr=zeros(size(config.floor(config.floor_exit).img_exit));
% build the exit_nr matrix
config.exit_nr = config.exit_nr + e*( img_build(:, :, 1) == 0 & img_build(:, :, 2) ==
(256-e) & img_build(:, :, 3) == 0 ) ;
```

Figure 1: Implementation of the *exit_nr* matrix

5.2.3 Closing exits during simulation**Reason:**

To close an exit as soon as it let a specific number of agents in, we have to keep track of the number of agents that already used this exit.

Function:

loadConfig.m and *applyForcesAndMove.m*

New variables:

exit_left

Modifications:

For this purpose, we defined the matrix *exit_left*, in which we store the number of agents who can exit for every exit.

```

%make a zeros vector as long as exit_count
config.exit_left = zeros(1,config.exit_count);
%loop over all exits
for e=1:config.exit_count
%build the exit_nr matrix
config.exit_nr = config.exit_nr + e*( img_build(:, :, 1) == 0 & img_build(:, :, 2) ==
(256-e) & img_build(:, :, 3) == 0 ) ;
%build the exit_left matrix and save the number of agents the exit can hold
config.exit_left(1,e) = config.(sprintf('exit_%d_nr', e));
end

```

Figure 2: Implementation of the exit_left matrix

In the loop where the forces and velocities are updated, (*applyForcesandMove.m*) we added a piece of code, which updates the exit_left matrix at every time-step. First, we get the number of the current exit.

```

%save current exit nr
data.current_exit = data.exit_nr(round(newp(1)), round(newp(2)));

```

Figure 3: Implementation to get the current exit number

Then we update the *exit_left* matrix by counting down the number of agents allowed to exit by 1. If the allowed number of agents exited the number is 0. Now we have

```

%update exit_left
data.exit_left(1,data.current_exit) = data.exit_left(1,data.exit_nr(round(newp(1)),
round(newp(2)))) - 1;

```

Figure 4: Implementation to update the exit_left

to close the current exit, by changing it into a wall. Therefore we have to update the *img_wall* matrix.

```

%close exit if there is no more free space
if data.exit_left(1,data.current_exit) < 1
%change current exit to wall
data.floor(data.floor_exit).img_wall = data.floor(data.floor_exit).img_wall == 1 ...
— (data.exit_nr == (data.current_exit));
data.floor(data.floor_exit).img_exit = data.floor(data.floor_exit).img_exit == 1 ...
& (data.exit_nr == (data.current_exit));

```

Figure 5: Implementation to close filled boats

5.3 Video creation

Reason:

In the basic code there was a graphical output into eps-formated files possible on every timestep. The images then had to be converted into a video file in a postprocessing part. This is not an optimal implementation for a fast system. Furthermore it turned out that we could increase the simulation speed by factor two just by saving not on every single timestep but only on every 10th or 100th. Another issue was the conversion from eps to a video file. To simplify the handling, we used a MATLAB function to create directly a video out of the figures instead of making a detour via images.

Function:

simulate.m, initialize.m

New variables:

save_frame

Modification:

```

% prepare video file name
data.video_file_name = ['video_' data.frame_basename '.avi'];

% make video while simulation
If data.save_frames==1
vidObj=VideoWriter(data.video_file_name);
open(vidObj);
end

% make video while simulate
currFrame=getframe(data.figure_floors);
writeVideo(vidObj,currFrame);

% make video while simulation
currFrame=getframe(data.figure_floors);
writeVideo(vidObj,currFrame);

% make video while simulation
close(vidObj);

```

Figure 6: Implementation to produce video file

5.4 System output

Reason:

Storing the simulation output is important to be able to analyse and optimize the system. The output of the basic code was just a plot with agents left the building over time and the above mentioned graphical output of the floor plans over time. We extended the output and created a dump struct where all the important variables are listed over time. That struct is the system output at simulation end and it can be used in a postprocessing part to generate meaningful graphs and data.

Function:

simulate.m

New variables:

output

Modification:

```
% init output matrices
data.output = struct;
data.output.config = config;
data.output.agents_per_floor = ones(data.floor_count,data.duration/data.dt).*(-1);
data.output.exit_left = zeros(data.exit_count,data.duration/data.dt);

% prepare output file name
data.output_file_name = ['output_' data.frame_basename];

% set deleted_agents to zero
data.output.deleted_agents = 0;

% dump agents_per_floor to output
for floor=1:data.floor_count
data.output.agents_per_floor(floor,data.step) = length(data.floor(floor).agents);
end

% dump exit_left to output
data.output.exit_left(:,data.step) = data.exit_left';

% toc of whole simulation
data.output.simulation_time = toc(simstart);

% save output
output = data.output;
save(data.output_file_name,'output')
fprintf('Frame %i done (took %.3fs; %.3fs out of %.3gs simulated). n',
data.step, data.telapsed, data.time, data.duration);

% save complete simulation
output = data.output;
save(textcolorstringcolor'output','output')
```

Figure 7: Implementation to produce the output

5.5 Postprocessing

Reason:

To analyse the gathered data in a systematic way and to create consistent plots we created a postprocessing file. The output file can be loaded in MATLAB using the load command and is thereafter automatically evaluated. Plots with agents per floor over time, left space in rescue boats over time and agents that left the ship over time are created with proper axis label and so on. Additionally there is an output in the MATLAB command window with timestep, number of steps, total simulation time, agents on ship on start, agents on ship on simulation end, agents deleted due to Not-a-Number-positions and the characteristic \$t_{10}\$, \$t_{50}\$, \$t_{90}\$ and \$t_{99}\$ times.

Function:

postprocessing.m

New variables:

none of relevance

Modification:

We created the whole script ourself. It can be found in the annex.

5.6 Parameter input and config file

The social force model can be adjusted using different parameters e.g. to weight the importance of different forces among each other or to define the decay rate of these forces over the distance. Also the mass and radii of the passengers as well as their maximal velocity can be set. The parameters are written down in the config files that are passed to the MATLAB interface on simulation start. For sake of simplicity we adopted the force model parameters for the previous group. The parameters concerning the ship shape were adjusted so that they represent reality as far as possible.

In the table in the annex a typical simulation input of the config file and some explanations can be found.

5.7 Ship Decks

Ship Deck Implementation:

The Costa Concordia has 14 decks which are all different from each other. They are connected by stairs and elevators in different configurations and they full fill different purposes. There are decks for entertainment, eating, shopping, sport and so on. Due to the big differences of each deck, it is enormous time consuming to implement all these decks with all details in a model. So it is necessary to simplify the decks in a reasonable manner. Further the picture source is not perfect in size and data type so

there is a manual conversion needed. In this chapter it is shown what assumptions were made and with which conversion techniques the decks were implemented into the model.

-Conversion

First of all the decks have to match each other in pixel size and position to allow a flawless connection of the decks. So the size of some decks has to be adjusted and the stair overlay has to be matched as good as possible. Secondly doors, numbers, names and symbols are removed to have one connected surface without unreal obstacles.

Now that the surfaces are clean and connected, the colours have to be replaced by predefined colours of the code. Violet for spawn of agents, black for walls, red for upstairs, blue for downstairs and different green type for each rescue boat.

In the Figures 8 and 9 a small portion of a deck with stairs, rooms, doors and elevators is shown before and after conversion. In the converted picture is a red one pixel row included for the stairs, which is hard to see because of low contrast. The stairs conversion will just be explained in the next part.

Figure 8: Deck before conversion

Figure 9: Deck after conversion

In most of the cases stairs from one to another floor are designed in a spiral way to minimize the consumed space. That leads to a problem by implementing the stairs into the model. It is not possible to make a clean transition from one floor to another without using some tricks.

In the work "Modeling Situations of Evacuation in a Multi-level Building" [3], which is the base of this project, are special additional floors to overcome the mentioned problem. These additional floors which represents the stairs, are a fine method to create an infinite amount of floors and connections without any trouble. But it needs that additional floor for each connection.

While there is a finite number of floors on the ship and the agents only march in

the direction of the rescue floor the connection can be simplified. So there is a new technique used to get rid of these additional floors.

In the Figure 10 a spiralling stairs connection between floor 01 and floor 02 is shown as example. The lines and arrows in light blue are used to clarify the technique. The agents arrive from the left on floor 01 and go into the direction of the arrow until they reach the red one pixel line. There they are skipped up on the floor 02 and try to go to the red one pixel line again. The line is now moved 2 pixels to the right and the agents go around to be skipped again on the floor 03 and so on. With that technique only a certain amount of floors can be realised corresponding to the pixel length of the stairs. But for the ship in that project it is sufficient, so that technique is used to implement the spiralling stairs.

Figure 10: Stairs connection between floor 01 and floor 02

-Similarities and Reduction

The most important floor for the simulation is of course floor 04 because it holds all the rescue boats as seen on the Figure 12. There all agents have to pass and it is reasonable to have it very detailed. Floor 05 and 03 are the ones just above and beyond and will also have a non neglectable influence on the agents movement.

The further we move the less important the deck configuration gets, because it is assumed that the stairs will be the bottlenecks. As long as the stairs correspond good to the reality, the further decks can differ more. So it is decided to convert deck 02, 03, 04 and 05 in detail and make a copy with adjusted stairs for each other floor. Floor 02 is used for the copy because it gets the closest to the floor 01, 06 and 07 and is by that still a good approximation.

Floor 08 until 14 differ more from floor 02 but as long as they are far away from floor 04 it will not have a big influence. These last floors are also smaller than floor

02 and therefore the amount of floors is reduced to only 11 with approximately the same area as the original 14 floors.

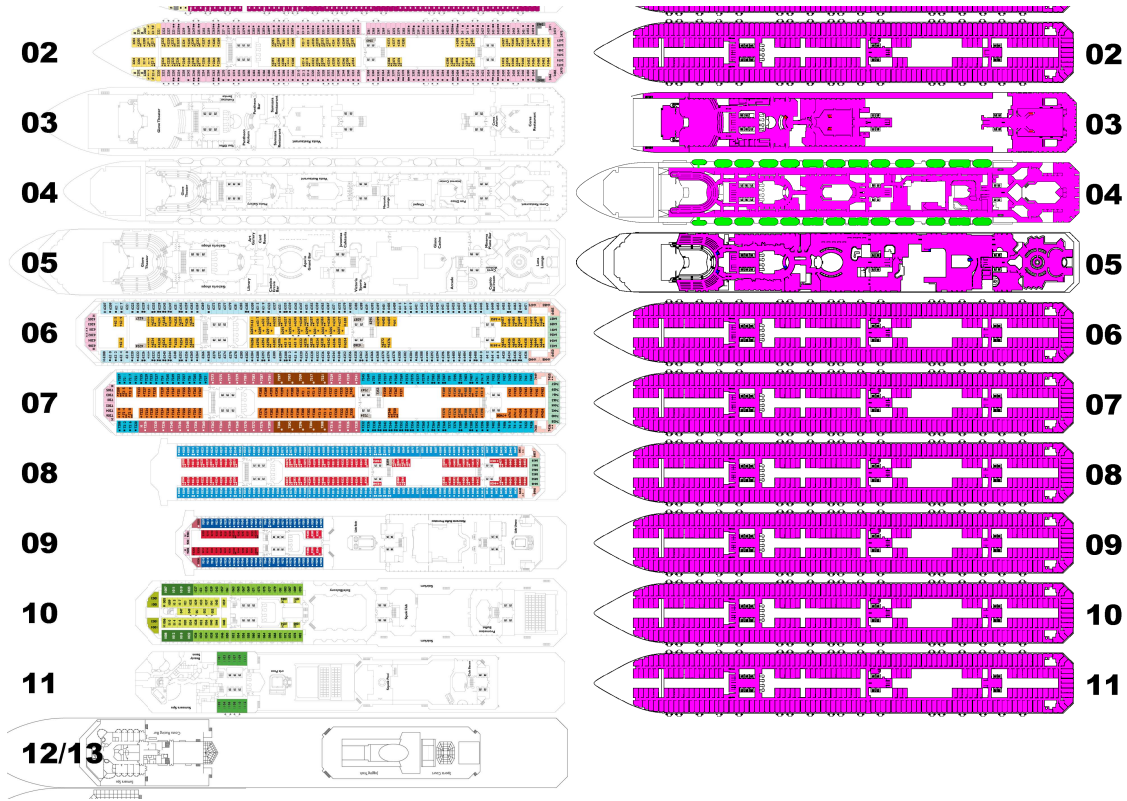

Figure 11: Original decks before conversion Figure 12: Deck approximated and converted

6 Simulation Results and Discussion

6.1 Expected Results

- Even though modern ships are quite optimized in regard to evacuation time, they are always a compromise between safety and luxury. Therefore we are convinced to find a superior adjustment of the decks geometries to increase the survival rate.
- Since the rescue boats can not be averaged but are rather concentrated over one or two decks, we consider the staircases as the bottlenecks.
- In alinging this variables we are persuaded of a reduction of the overall evacuation time.
- We suppose that smaller and evenly spread rescue boats combined with a higher quantity will scale the evacuation time down. Certainly there is going to be an optimum in size which we are willing to find.
- By controlling the rescue we assume to detect a huge decrease in evacuation time. Further we have the hypothesis that disorder can be minimized. The crew who is familiar with the decks and the emergency exits is able to guide the passengers in minimum time to the rescue boats.
- There are many parameters we do not model in our simulation. For example fire and smoke, the tilt of the ship or handicapped and petrified passengers are disregarded. By leaving out this details we get a very simplified model. However, by starting the optimization process by data of a nowadays passenger liner [6] we hope to see some real evacuation dynamics in this system and therefore make conclusion on the fundamental questions.

6.2 Simulation Results

6.2.1 Standard ship

As listed above we were interested in the time in which a certain percentage of all agents was evacuated:

percentage of agents.	10%	50%	90%	99%
evacuation time	69s	272s	468s	614s

Table 1: Standard simulation: Needed time to evacuate a certain percentage of all agents.

Further our standard ship simulation showed the following performance:

Figure 13: Standard simulation: Boat capacities during simulation

Figure 14: Standard simulation: Number of agents per floor

6.2.2 Modified room disposition

As we expected the standard simulation revealed that hold-up problems occur because of the staircases. As the flow everywhere else was quite dynamic we abstained from adjusting the room disposition but instead we inserted an additional staircase. This simulation yielded the following results:

percentage of agents.	10%	50%	90%	99%
evacuation time	72s	259s	461s	595s

Table 2: Added stairs simulation: Needed time to evacuate a certain percentage of all agents.

Figure 15: Added stairs simulation: Boat capacities during simulation

Figure 16: Added stairs simulation: Number of agents per floor

6.2.3 Modified rescueboat size

As we could see in the simulations with the standard ship, the rescueboats which are nearest to the stairs are filled first. This behavior is very intuitive. As soon as the nearest lifeboats are full, the agents continue to fill the other lifeboats. The greatest extension of the evacuation time occurs as follows: Towards the end of the simulation, not all lifeboats are still open. Therefore leftover agents, which walked in the direction of a lifeboat that closed in the meantime, have to cross a big distance to reach a lifeboat with free space.

We tried to avoid this delay by increasing the capacity of the lifeboats near to the stairs and removed some, which are the farthest away for the agents left over towards the end of the evacuation.

percentage of agents.	10%	50%	90%	99%
evacuation time	71.44s	257.12s	419.4s	571.4s

Table 3: Varied boatsize simulation: Needed time to evacuate a certain percentage of all agents.

6.2.4 Crew command

6.3 Comparison

6.3.1 Standard - Modified room disposition

The Analysis of the simulation results showed that there is a huge potential in saving evacuation time. By adding just one additional staircase we were able to reduce the overall evacuation time by almost 20 seconds. Further 50% of all agents entered the exits approximately 13 seconds earlier compared to the standard model. In contrast to that the rescueboat capacity utilisation remains basically the same. Another point which was actually not important for our research is that you get a much higher agent density on the exit floor.

6.3.2 Standard - Modified rescueboat size

As the results above show, there is no significant acceleration in the first part of the evacuation achieved by changing the distribution of the lifeboats. But, there is clearly a difference in second half of the evacuation. The last 10% of agents are evacuated 48.6 seconds faster and the last 1% even 42.6 seconds faster. This decrease in evacuation time is an effect of the reduced time the last agents need to leave the exit-deck.

6.3.3 Standard - Crew command

6.4 Discussion

7 Summary and Outlook

7.1 Summary

7.2 Outlook

During our work on this project, we found a lot of possibilities to improve the model. The target of an ongoing project could be to make the model more realistic. There are a lot of possibilities to achieve this goal.

Some suggestions:

- To take into account that not all people automatically know where exactly the nearest exit is, the initialisation of the escape routes should be modified.
- In our model the agents are evenly distributed over the floors and decks at the beginning of the simulation. This is however a very unrealistic scenario. In

reality the agents will be unevenly spread. The evacuation time would depend very much on the form of this distribution.

- Different scenarios like night, dinner-time etc. that would change the distribution of the agents significantly could be compared.
- In reality there are a lot of effects that could occur like fire, tilt of the ship, flooded areas, power failure, mass panic etc.

There are a lot of other interesting effects that could be looked at as well.

Some ideas:

- In the ideal case, the evacuations on a ship are planned well. A good idea would be to define specific control points at which agents gather first. From those points the agents would be led in small groups to the rescueboats by a crew member. It would be interesting to analyse the effect of such a efficient control.
- The optimal combination of the different modifications we analyzed in this project could be found and therefore a minimal evacuation time.
